#### Abstract

The crystal structure of $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$ (monoclinic, $C 112_{1}, a=5.791(2), b=12.998(4), c=19.330(6) \AA, \gamma=90.089(3)^{\circ}$, $\left.V=1455.1(8) \AA^{3}\right)$ has been solved by direct methods and refined to $R 1=0.061$ using X-ray diffraction data collected from a crystal twinned on (010). There are seven symmetrically independent $\mathrm{Pb}^{2+}$ cations in the structure. Each has a strongly distorted coordination polyhedron due to stereochemically active $s^{2}$ lone electron pairs on the $\mathrm{Pb}^{2+}$ cations. The structure is based on $\left[\mathrm{O}_{2} \mathrm{~Pb}_{3}\right]$ double chains extending along [100] formed by edge-sharing $\left(\mathrm{OPb}_{4}\right)$ oxocentered tetrahedra. Hydroxyl groups form two short $(\mathrm{OH})-\mathrm{Pb}$ bonds that result in $(\mathrm{OH}) \mathrm{Pb}_{2}$ dimers. The $(\mathrm{OH}) \mathrm{Pb}_{2}$ dimers link the $\left[\mathrm{O}_{2} \mathrm{~Pb}_{3}\right]$ chains into a three-dimensional framework with channels parallel to [100] that are occupied by $\mathrm{Cl}^{-}$anions.

Key-words: lead oxide chlorides, crystal structure, lone electron pairs, oxocentered tetrahedra.

## Introduction

The basic lead chloride dihydrate with a $\mathrm{Pb}: \mathrm{Cl}$ ratio of 7:2 is one of the major phases reported in the $\mathrm{PbO}-\mathrm{H}_{2} \mathrm{O}-\mathrm{HCl}$ system [see, e.g. Tavernier \& de Jaeger (1976) and Kiyama et al. (1976)]. Shrier (1963) reported the compound $\mathrm{Pb}_{7} \mathrm{O}_{6} \mathrm{Cl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ as a corrosion product of buried lead cable sheaths. Edwards et al. (1992) obtained $\mathrm{Pb}_{7} \mathrm{O}_{6} \mathrm{Cl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ as a product of titration of aqueous lead chloride solutions with aqueous sodium hydroxide at $25^{\circ} \mathrm{C}$ in a $\mathrm{CO}_{2}$-free environment. These authors also determined stability constants for this compound at 298.2 K and $P=10^{5} \mathrm{~Pa}$.

The phase $\mathrm{Pb}_{7} \mathrm{O}_{6} \mathrm{Cl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ is a dihydrated chemical analogue of "lorettoite", $\mathrm{Pb}_{7} \mathrm{O}_{6} \mathrm{Cl}_{2}$, which was first reported by Wells \& Larsen (1916) and later discredited by White (1979) owing to its anthropogenic origins "on the basis of its physical appearance, associations, and total absence of any tie to a natural occurrence". Later, Schnorrer-Köhler (1986) and Schnorrer-Köhler et al. (1988) reported "lorettoite" in the Larium lead slags. It should be noted that the powderdiffraction pattern for "lorettoite", $\mathrm{Pb}_{7} \mathrm{O}_{6} \mathrm{Cl}_{2}$ (JCPDS 6-393) is quite different from that of $\mathrm{Pb}_{7} \mathrm{O}_{6} \mathrm{Cl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (JCPDS 330767).

As a part of our ongoing study of lead oxide chlorides (Krivovichev \& Burns, 2001a), we have synthesized a phase with the crystal chemical formula $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$ that is identical to the phase $\mathrm{Pb}_{7} \mathrm{O}_{6} \mathrm{Cl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ reported by Edwards et al. (1992).

## Experimental

## Synthesis

Single crystals of $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$ were obtained by hydrothermal methods from a mixture of 0.1 g of PbO (red), 0.06 g of $\mathrm{Sr}\left(\mathrm{NO}_{3}\right), 0.06 \mathrm{~g}$ of KCl with 5 ml of $\mathrm{H}_{2} \mathrm{O}$. The reactants were placed in a 23 ml Teflon-lined Parr bomb and were heated to $230^{\circ} \mathrm{C}$ for 12 days. The products were filtered and washed with ultrapure water. The crystals of $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$ occurred as white semi-transparent needles up to 1.2 mm long elongated in [100]. As it was consequently confirmed by structure analysis, the crystals are invariably twinned along (010) plane. The twinning should be referred as nonmerohedral, i.e. twin operator is a symmetry operator of the higher crystal system than one of the crystal.

## Data collection

A suitable crystal of $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$ was mounted on a Bruker three-circle CCD-based X-ray diffractometer operated at 50 kV and 40 mA . More than a hemisphere of three-dimensional data was collected using monochromatic MoKa X-radiation, with frame widths of $0.3^{\circ}$ in $\omega$, and with 30 seconds spent counting for each frame. The unit-cell parameters (Table 1) were refined with 949 reflections using leastsquares techniques. The intensity data were integrated and corrected for Lorentz, polarization, and background effects

using the Bruker program SAINT. A semi-empirical absorp-tion-correction was done based upon 642 intense reflections. The crystal was modeled as an ellipsoid, which lowered the $R_{\text {azimuthal }}$ from 18.8 to $9.2 \%$.

## Structure solution and refinement

The Bruker SHELXTL Version 5 system of programs was used for the determination and refinement of the crystal structure. Systematic absences of reflections indicated space group $C 222_{1}$, but we were unable to solve the structure in this space group. It was assumed that the structure is monoclinic and direct methods were used to obtain the Pb positions in space group $\mathrm{Cl12}_{1}$. Refinement of the Pb positional parameters and isotropic displacement parameters gave an agreement index ( $R 1$ ) of $13.4 \%$, but we were unable to satisfactorily locate the anions in difference-Fourier maps calculated following refinement of the model. Examination of the calculated and observed structure factors revealed that the largest discrepancies corresponded to $F_{\text {obs }}$ that were much greater than $F_{\text {calc }}$, a situation that is common when dealing with a twinned crystal involving the superposition of two or more reciprocal lattices. We incorporated twinning with the operator [100 0-10 001] using the method of Jameson (1982) and Herbst-Irmer \& Sheldrick (1998), which lowered the $R 1$ to $9.1 \%$ and permitted determination of anion locations in the difference-Fourier maps. The final model included all atomic positional parameters, anisotropicdisplacement parameters for Pb and Cl , and a refinable weighting scheme of the structure factors. The model was refined on the basis of $F^{2}$ for all 2420 unique reflections. The final refinement converged to an $R 1$ of 0.061 , calculated for the 1514 unique observed $\left(|F \mathrm{o}| \geq 4 \sigma_{F}\right)$ reflections. The final atomic coordinates and anisotropic displacement parameters are in Table 2, selected interatomic distances are in Table 3, and a bond-valence analysis is provided in Table 4. A table of calculated and observed structure factors is avail-

## Results

## Cation polyhedra

There are seven symmetrically independent $\mathrm{Pb}^{2+}$ cations in the structure of $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$ (Fig. 1). The coordination polyhedron about each $\mathrm{Pb}^{2+}$ cation contains three or four short ( 2.16 to $2.55 \AA$ ) bonds, all of which are on one side of the cation owing to the presence of stereochemically active $s^{2}$ lone-electron pairs on the cations. $\mathrm{The} \mathrm{Pb}(1)$ and $\mathrm{Pb}(2)$ cations are strongly bonded to four atoms of O , resulting in $\mathrm{PbO}_{4}$ tetrahedral pyramids with the $\mathrm{Pb}^{2+}$ cation at the apical vertex (Fig. 1). Three Cl atoms are located from 3.39 to 3.62 $\AA$ from each of the $\mathrm{Pb}(1)$ and $\mathrm{Pb}(2)$ cations, on the opposite side of the polyhedron from the O atoms. The bond-valence parameters given by Brese \& O'Keeffe (1991) indicate these Cl atoms are bonded to the $\mathrm{Pb}^{2+}$ cations, with bond valences ranging from 0.05 to 0.10 vu . Note that omission of these long bonds would result in significant underbonding of the $\mathrm{Pb}^{2+}$ cations. $\mathrm{The} \mathrm{Pb}(3)$ and $\mathrm{Pb}(4)$ cations are each bonded to two O atoms and one hydroxyl group, with bond lengths

ranging from 2.20 to $2.33 \AA$. Each of these cations are also weakly bonded to three Cl anions with bond lengths of 3.33 to $3.59 \AA$, corresponding to bond valences of 0.06 to 0.12 $v u$. $\mathrm{The} \mathrm{Pb}(5)$ and $\mathrm{Pb}(6)$ cations are each strongly bonded to two O atoms and one hydroxyl group, with bond lengths in the range 2.16 to 2.30 A. These cations are each weakly bonded to two hydroxyl groups, with bond lengths of 3.10 to $3.31 \AA$ Ahat correspond to 0.07 to 0.10 vu , and one Cl anion with bond lengths of 3.24 and $3.39 \AA$ A. Finally, the $\mathrm{Pb}(7)$ cation is coordinated only by four hydroxyl groups with bond lengths in the range 2.20 to 2.55 A .

Fig. 1. Coordination polyhedra about the $\mathrm{Pb}^{2+}$ cations in $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$. Legend: $\mathrm{Pb}-$ small dark circles, $\mathrm{Cl}-$ large dark circles, O - large light circles.

## Bond valence analysis

The bond valence analysis presented in Table 4 was calculated using the parameters for $\mathrm{Pb}^{2+}-\mathrm{O}$ bonds from Krivovichev \& Brown (2001), and for $\mathrm{Pb}^{2+}-\mathrm{Cl}$ bonds from Brese \& O'Keeffe (1991). The bond-valence sums for the $\mathrm{Pb}^{2+}$ cations range from 1.77 to $2.08 v u$, typical values for $\mathrm{Pb}^{2+}$ in similar structures. The bond-valence sums at the anion sites readily permit distinction of O atoms ( 1.95 to 2.01 vu ) and hydroxyl groups ( 0.98 to 1.14 vu ). The bond-valences incident upon the Cl sites are 0.76 and 0.51 vu , indicating either that these anions probably accept H bonds donated by the hydroxyl groups or that the $\mathrm{Pb}^{2+}-\mathrm{Cl}$ bond valence parameters given by Brese \& O'Keeffe (1991) are insufficiently flexible. The first suggestion is supported for the $\mathrm{Cl}(2)$ an-
ions by the existence of two OH groups locating from the $\mathrm{Cl}(2)$ anion at 3.14 and $3.35 \AA$.

## Structure description

Fig. 1 shows that the coordination polyhedra of cations are very irregular due to the stereochemical activity of $s^{2}$ lone electron pairs. Table 4 demonstrates that the bond-valence distribution in these polyhedra is such that the strong $\mathrm{Pb}-\mathrm{O}$ and $\mathrm{Pb}-\mathrm{OH}$ bonds (bond valences in the range of $0.30-0.67$ $\nu u$ ) are located on one side of coordination sphere only, whereas opposite site is occupied by weak $\mathrm{Pb}-\mathrm{OH}$ and $\mathrm{Pb}-\mathrm{Cl}$ bonds (bond valences < 0.15 vu ). This makes reasonable to describe the structure in terms of strong $\mathrm{Pb}-\mathrm{O} / \mathrm{OH}$ bond systems rather than in terms of coordination polyhedra of cations. It appears that the O atoms in the structure of $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$ are tetrahedrally coordinated by four Pb atoms that result in $\left(\mathrm{OPb}_{4}\right)$ tetrahedra, whereas the OH groups form two short $(\mathrm{OH})-\mathrm{Pb}$ bonds that result in $(\mathrm{OH}) \mathrm{Pb}_{2}$ dimers. It should be noted that the $\mathrm{OH}(5)$ and $\mathrm{OH}(6)$ groups form two short ( OH ) -Pb bonds only, whereas the $\mathrm{OH}(7)$ and $\mathrm{OH}(8)$ groups form two additional weak $(\mathrm{OH})-\mathrm{Pb}$ bonds with distance of $>3.10 \AA$. Both these types of O and OH coordinations are typical for structures containing 'additional' O atoms (i.e. not bonded to high-valent cations such as $\mathrm{Si}^{4+}$, $\mathrm{S}^{6+}, \mathrm{N}^{5+}, \mathrm{C}^{4+}$, etc.) and OH groups (Keller, 1982, 1983; Riebe \& Keller, 1988, 1989; Langecker \& Keller, 1994; Vassilev \& Nihtianova, 1998; Li et al., 2000, 2001; Krivovichev et al., 2001; Krivovichev \& Burns, 2000a, b, 2001a, b).

The structure of $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$ is based on double chains of composition $\left[\mathrm{O}_{2} \mathrm{~Pb}_{3}\right]$ formed by edge-sharing $\left(\mathrm{OPb}_{4}\right)$ oxocentered tetrahedra (Fig. 2). The chains extend along [100] with the chain width parallel to (010) (Fig. 3). The ( OH ) $\mathrm{Pb}_{2}$ dimers link the $\left[\mathrm{O}_{2} \mathrm{~Pb}_{3}\right]$ chains into a three-dimensional framework (Fig. 3). We note that these links involve the $\mathrm{Pb}(7)$ cation that is coordinated only by four hydroxyl groups and that does not participate in a $\left(\mathrm{OPb}_{4}\right)$ tetrahedron (Fig. 1). The resulting $\mathrm{Pb}-\mathrm{O} / \mathrm{OH}$ framework has channels parallel to [100] that contain $\mathrm{Cl}^{-}$anions.

## Structural geometry of $\left(\mathrm{OPb}_{4}\right)$ tetrahedra

Figure 2 shows connectivity diagrams for tetrahedra that build the $\left[\mathrm{O}_{2} \mathrm{~Pb}_{3}\right]$ chains in $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$. The $\mathrm{O}-\mathrm{Pb}$ distances from the central O anions to the $\mathrm{Pb}^{2+}$ cations in the $\left(\mathrm{OPb}_{4}\right)$ tetrahedra are written near the corners. It is clear that an increase in the number of tetrahedra sharing a corner correlates with an increase of the $\mathrm{O}-\mathrm{Pb}$ bond length; this is common for structural units based upon oxocentered $\left(\mathrm{OM}_{4}\right)$ tetrahedra (Krivovichev et al., 1998).

The mean $\mathrm{Pb} \cdots \mathrm{Pb}$ distances for $\left(\mathrm{OPb}_{4}\right)$ tetrahedra in $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$ are 3.72, 3.78, 3.77 and $3.78 \AA$ for the $\left[\mathrm{O}(1) \mathrm{Pb}_{4}\right],\left[\mathrm{O}(2) \mathrm{Pb}_{4}\right],\left[\mathrm{O}(3) \mathrm{Pb}_{4}\right]$ and $\left[\mathrm{O}(4) \mathrm{Pb}_{4}\right]$ tetrahedra, respectively, in accord with the value of $3.74 \AA$ given by Krivovichev \& Filatov (1999).

The average $\mathrm{Pb}-\mathrm{O}-\mathrm{Pb}$ bond angles in the $\left(\mathrm{OPb}_{4}\right)$ tetrahedra are in the range of $109.4-109.6^{\circ}$, whereas individual $\mathrm{Pb}-$ $\mathrm{O}-\mathrm{Pb}$ angles are in the range of $98.9-122.5^{\circ}$. The $\mathrm{Pb}-\mathrm{OH}-\mathrm{Pb}$

Fig. 2. The $\left[\mathrm{O}_{2} \mathrm{~Pb}_{3}\right]$ chain of $\left(\mathrm{OPb}_{4}\right)$ oxocentered tetrahedra shown in a ball-and-stick representation, and connectivity diagrams for the $\left(\mathrm{OPb}_{4}\right)$ tetrahedra in $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$.

Fig. 3. The crystal structure of $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$ projected along the $a$ axis. Legend: Pb - small dark circles, Cl - large dark circles, O large light circles; double bonds - strong $\mathrm{Pb}-\mathrm{O} / \mathrm{OH}$ bonds ( $<2.6 \AA$ ), single bonds - weak $\mathrm{Pb}-\mathrm{OH}$ and $\mathrm{Pb}-\mathrm{Cl}$ bonds (> $3.1 \AA$ ); possible directions of the $\mathrm{Cl}(2) \cdots \mathrm{H}-\mathrm{O}$ hydrogen bonds are shown by dashed lines.
angles in the $(\mathrm{OH}) \mathrm{Pb}_{2}$ dimers are $125.7,126.3,138.5$ and $130.3^{\circ}$ for $\mathrm{OH}(5), \mathrm{OH}(6), \mathrm{OH}(7)$ and $\mathrm{OH}(8)$ groups, respectively.

## Discussion

$\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$ is a new member of the structural family of minerals and synthetic compounds that are based upon the $\left[\mathrm{O}_{2} \mathrm{~Pb}_{3}\right]$ double chains of $\left(\mathrm{OPb}_{4}\right)$ oxocentered tetrahedra [see Krivovichev \& Burns (2001a) for more details]. Amongst lead oxide chlorides, these chains have been previously observed in damaraite and mendipite (Keller et al., 2000, 2001; Pasero \& Vacchiano, 2000; Krivovichev \& Burns, 2001a). However, in mendipite and damaraite the [ $\mathrm{O}_{2} \mathrm{~Pb}_{3}$ ] chains occur in two non-parallel orientations, whereas in $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$ the chains are parallel to each other. The $\left[\mathrm{O}_{2} \mathrm{~Pb}_{3}\right]$ chains in mendipite are isolated, whereas in damaraite they are linked by $(\mathrm{OH}) \mathrm{Pb}_{2}$ dimers to form
$\left[\left(\mathrm{Pb}_{3} \mathrm{O}_{2}\right)(\mathrm{OH})\right]$ sheets. In contrast, $\mathrm{Pb}_{7} \mathrm{O}_{4}(\mathrm{OH})_{4} \mathrm{Cl}_{2}$ is the first compound in which $\left[\mathrm{O}_{2} \mathrm{~Pb}_{3}\right]$ chains are interlinked by $(\mathrm{OH}) \mathrm{Pb}_{2}$ dimers to form a three-dimensional framework.
